OS19 Excision of a Ganglion

What is a ganglion?
A ganglion is a lump under the skin that contains fluid.
Your surgeon has recommended an operation to remove your ganglion. However, it is your decision to go ahead with the operation or not. This document will give you information about the benefits and risks to help you make an informed decision.
If you have any questions that this document does not answer, you should ask your surgeon or any member of the healthcare team.

How does a ganglion happen?
Ganglions usually form near joints. 3 out of 4 ganglions form near the wrist joint (see figure 1). They are also found on the ankle and foot.

The fluid in the ganglion comes from the joint through a narrow channel. Some ganglions happen after an injury such as a sprain, but most appear without a known cause.

What are the benefits of surgery?
The lump and any discomfort from it should disappear. Surgery gives the best chance of stopping the ganglion coming back.

Are there any alternatives to surgery?
A ganglion will often disappear on its own after a year or two. If your ganglion is not causing much trouble it is best to leave it alone.
The fluid can be taken out of the ganglion using a needle. This confirms that the lump is a ganglion and improves any discomfort for a while. Your doctor may also inject the ganglion with a steroid (cortisone). These treatments may help for a short time but the ganglion often comes back.

What will happen if I decide not to have the operation?
A ganglion is not serious. It will often disappear on its own.

What does the operation involve?
A variety of anaesthetic techniques are possible. Your anaesthetist will discuss the options with you and will recommend the best form of anaesthesia for you. The operation usually takes between a quarter of an hour and half an hour.
Your surgeon will make a cut over the ganglion and carefully separate the ganglion from the nearby tendons, nerves and blood vessels. They will then remove the ganglion from where it comes out of the joint.
The place where the ganglion is actually removed could be a little way from where you can feel the main lump, so the cut may need to be bigger than you expected.
At the end of the operation, your surgeon will close the skin with stitches.

What should I do about my medication?
You should continue your normal medication unless you are told otherwise.
Let your surgeon know if you are on warfarin or clopidogrel. Follow your surgeon’s advice about stopping this medication before the operation.

What can I do to help make the operation a success?

• **Lifestyle changes**
  If you smoke, try to stop smoking now. Stopping smoking several weeks or more before an operation may reduce your chances of getting complications and will improve your long-term health.
  For help and advice on stopping smoking, go to www.gosmokefree.co.uk.
  You have a higher chance of developing complications if you are overweight.
  For advice on maintaining a healthy weight, go to www.eatwell.gov.uk.

• **Exercise**
  Regular exercise can reduce the risk of heart disease and other medical conditions, improve how your lungs work, boost your immune system, help you to control your weight and improve your mood. Exercise should help to prepare you for the operation, help with your recovery and improve your long-term health.
  For information on how exercise can help you, go to www.eidoactive.co.uk.
  Before you start exercising, you should ask a member of the healthcare team or your GP for advice.

What complications can happen?
The healthcare team will try to make your operation as safe as possible. However, complications can happen. Some of these can be serious. You should ask your doctor if there is anything you do not understand. Any numbers which relate to risk are from studies of people who have had this operation. Your doctor may be able to tell you if the risk of a complication is higher or lower for you.

The complications fall into three categories.
1 Complications of anaesthesia
2 General complications of any operation
3 Specific complications of this operation

1 **Complications of anaesthesia**
Your anaesthetist will be able to discuss with you the possible complications of having an anaesthetic.

2 **General complications of any operation**

• **Pain**, which happens with every operation. The healthcare team will try to reduce your pain. They will give you medication to control the pain and it is important that you take it as you are told so you can move about as advised.
  • **Bleeding** during or after surgery.
  • **Infection in the wound**. If this happens, you may need antibiotics or another operation.
  • **Unsightly scarring** of the skin. This can sometimes be a problem if the scar is on the front of your wrist.

3 **Specific complications of this operation**

• **Damage to small nerves near the ganglion**. If this happens, you may get a small patch of numbness or a painful scar (risk: 1 in 15). This usually gets better with time but occasionally can be permanent.

How soon will I recover?

• **In hospital**
  After the operation you will be transferred to the recovery area and then to the ward. It is important to keep your arm or leg lifted up to reduce swelling. You should be able to go home the same day. However, your doctor may recommend that you stay a little longer.
  If you are worried about anything, in hospital or at home, ask a member of the healthcare team. They should be able to reassure you or identify and treat any complications.
• Returning to normal activities
Your surgeon, physiotherapist and occupational therapist will tell you when you can return to normal activities. Your surgeon will tell you if there are any stitches that need to be removed. Any joint stiffness should get better fairly quickly. Regular exercise should help you to return to normal activities as soon as possible. Before you start exercising, you should ask a member of the healthcare team or your GP for advice. Do not drive until you are confident about controlling your vehicle and always check with your doctor and insurance company first.

• The future
The scar can look quite thick for a few months, especially if it is on the front of your wrist. The joint where the ganglion was can continue to ache. This may happen because of wear and tear of the joint itself. Some ganglions come back after a few months or years (risk: 1 in 10).

Summary
A ganglion is not serious. If it is causing trouble, your surgeon can remove it. Surgery is usually safe and effective. However, complications can happen. You need to know about them to help you to make an informed decision about surgery. Knowing about them will also help to detect and treat any problems early.
